## ACKNOWLEDGEMENT

I would like to express my sincere gratitude to **Dr. Jayadeep Pati**, Assistant Professor and Registrar In-Charge at the Indian Institute of Information Technology Ranchi, for his invaluable guidance, encouragement, and continuous support throughout the course of this minor project. His insightful suggestions, constructive feedback, and constant motivation played a crucial role in shaping this work and ensuring its successful completion.

I would also like to thank the faculty members of the Department of Computer Science and Engineering, IIIT Ranchi, for providing a strong academic foundation and a supportive learning environment that encouraged exploration and practical application of machine learning concepts.

Finally, I am grateful to my peers and all those who directly or indirectly contributed to this project titled **“Credit Card Fraud Detection using Machine Learning.”** Their support and cooperation were instrumental in the completion of this work.

## **ABSTRACT**

Credit card fraud is a major problem, with billions of dollars lost each year. Machine learning can be used to detect credit card fraud by identifying patterns that are indicative of fraudulent transactions. Credit card fraud refers to the physical loss of credit card or loss of sensitive credit card information. Many machine- learning algorithms can be used for detection. This project proposes to develop a machine learning model to detect credit card fraud. The model will be trained on a dataset of historical credit card transactions, and it will be evaluated on a holdout dataset of unseen transactions.

## INTRODUCTION

'Fraud' in credit card transactions is unauthorized and unwanted usage of an account by someone other than the owner of that account. Fraud has been increasing drastically with the progression of state-of-art technology and worldwide communication. Credit cards are one of the most popular objectives of fraud but not the only one. Credit card fraud, wide-ranging term for theft and fraud committed or any similar payment mechanism as a fraudulent resource of funds in a transaction.

Credit card fraud has been expanding issue in the credit card industry. Detecting credit card fraud is a difficult task when using normal process, so the development of the credit card fraud detection models has become of importance whether in the academic or business organizations currently. Fraud can be avoided in two main ways: prevention and detection. Prevention avoids any attacks from fraudsters by acting as a layer of protection. Detection happens once the prevention has already failed. Therefore, detection helps in identifying and alerting as soon as a fraudulent transaction is being triggered.

Machine learning is this generation's solution which replaces such methodologies and can work on large datasets which is not easily possible for human beings. Machine learning techniques fall into two main categories: supervised learning and unsupervised learning. Fraud detection can be done in either way and only can be decided when to use according to the dataset. Supervised learning requires prior classification to anomalies. During the last few years, several supervised algorithms have been used in detecting credit card fraud. The data which is being used in this study is analyzed in two main ways: as categorical data and as numerical data. The dataset originally comes with categorical data. The raw data can be prepared by data cleaning and other basic preprocessing techniques. First, categorical data can be transformed into numerical data and then appropriate techniques are applied to do the evaluation. Secondly, categorical data is used in the machine learning techniques to find the optimal algorithm.

This project consists of selecting optimal algorithms for fraud patterns through an extensive comparison of machine learning such as Logistic Regression, KNN Neighbors, Decision Tree. Techniques via an effective performance measure for the detection of fraudulent credit card transactions. The rest of this paper is presented as follows. Section 2 presents the literature review. Section 3 provides the experimental methodology including results. Finally, conclusions and discussions of the paper are presented in Section 4.

## LITERATURE REVIEW

In earlier studies, many approaches have been proposed to bring solutions to detect fraud from supervised approaches, unsupervised approaches to hybrid ones, which makes it a must to learn the technologies associated in credit card frauds detection and to have a clear understanding of the types of credit card fraud. With the analysis of various detection models, past researchers have found many problems regarding fraud detection. Classical algorithms such as Support Vector Machines (SVM), Decision Tree (DT), LR and RF proven useful.

In paper [1], European dataset was also used, and comparison was made between the models based on LR, DT and RF. Among the three models, RF proved to be the best, with accuracy of 95.5%, followed by DT with 94.3% and LR with accuracy of 90%.

According to [2] and [3], k-Nearest neighbors (KNN) and outlier detection techniques can also be efficient in fraud detection. They are proven useful in minimizing false alarm rates and increasing fraud detection rate.

KNN algorithm also performed well in experiment for paper [4], where the authors tested and compared it with other classical algorithms. The paper [5] discussed commonly used supervised techniques and they have provided a thorough evaluation of supervised learning techniques. Also, they have shown that all algorithms change according to the problem area.

Fraud detection system presented in paper [6] is built to handle class imbalance, the formation of labelled and unlabeled, and processing of large datasets. The proposed system was able to overcome all the challenges.

In paper [7] they have highlighted fraud detection cost and lack of adaptability as challenges in the fraud detection process. When considering a system, the cost of fraudulent behavior and the prevention cost should be taken into consideration. Lack of adaptability occurs when the algorithm is exposed to new types of fraud patterns and normal transactions.

## PROPOSED METHODS

In this project we will use three different Algorithms to find out the prediction of a card to real or fraud. Description of these Algorithms are given below:

### Logistic Regression:

This statistical classification model based on probabilities detects the fraud using logistic curve. Since the value of this logistic curve varies from 0 to 1, it can be used to interpret class membership probabilities. The dataset fed as input to the model is being classified for training and testing the model. Post model training, it is tested for some minimum threshold cut-off value for prediction. Since the logistic regression, based on some threshold probabilities can divide the plane using a single line and divides dataset points into exactly two regions.

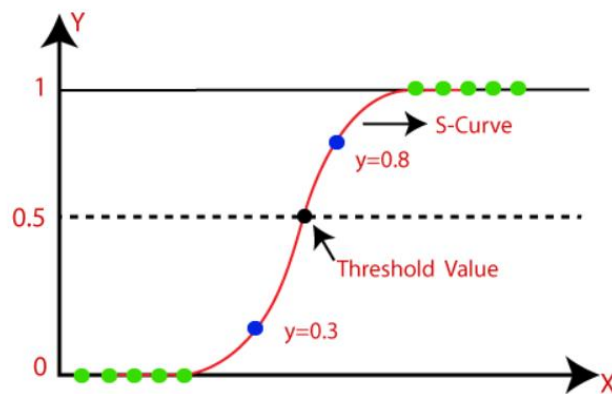

Fig: The logistic regression model

## K-Nearest Neighbor (KNN):

This is a supervised learning technique that achieves consistently high performance in comparison to other fraud detection techniques of supervised statistical pattern recognition [24]. Three factors majorly affect its performance distance to identify the least distant neighbors, some rule to deduce a categorization from k-nearest neighbor & the count of neighbors to label the new sample. This algorithm classifies any transactions that occurred by computing the least distant point to this particular transaction and if this least distant neighbor is classified as fraudulent then the new transaction is also labeled as a fraudulent one. Euclidean distance is a good choice to calculate the distances in this scenario. This technique is fast and results in fault alerts. Its performance can be improved by distance metric optimization.

## Discission Tree:

A supervised learning algorithm, A decision tree which is in the form of tree structure, consisting of root node and other nodes split in a binary or multi-split manner further into child nodes with each tree using its own algorithm to perform the splitting process. With the tree growing, there may be possibilities of overfitting of the training data with possible anomalies in branches, some errors or noise. Hence pruning is used for improving classification performance of the tree by removing certain nodes. Ease in the use, and the flexibility that the decision trees provide to handle different data types of attributes make them quite popular.

## Support Vector Machine:

Support vector machines or SVMs are linear classifiers as stated in that work in high dimensionality because in high-dimensions, a non-linear task in input becomes linear and hence this makes SVMs highly useful for detecting frauds. Due to its two most important features that is a kernel function to represent classification function in the dot product of input data point projection, and the fact that it tries finding a hyperplane to maximize separation between classes while minimizing overfitting of training data, it provides a very high generalization capability.

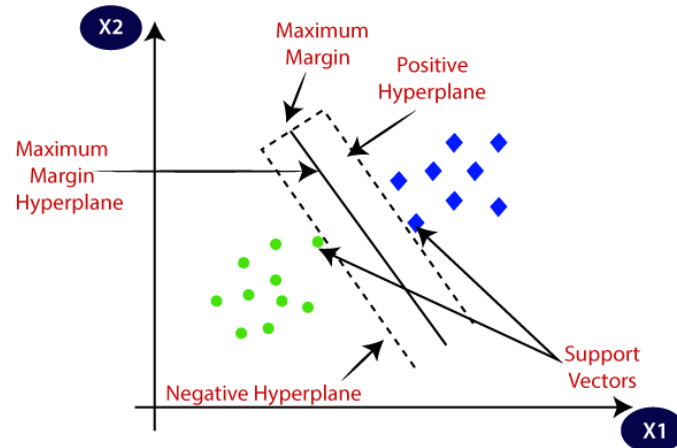

Fig: Support Vector Machine algorithm.

## Dataset:

In this research the Credit Card Fraud Detection dataset was used, which can be downloaded from Kaggle [8]. This dataset contains transactions, occurred in two days, made in September 2013 by European cardholders.

## PROJECT PLAN

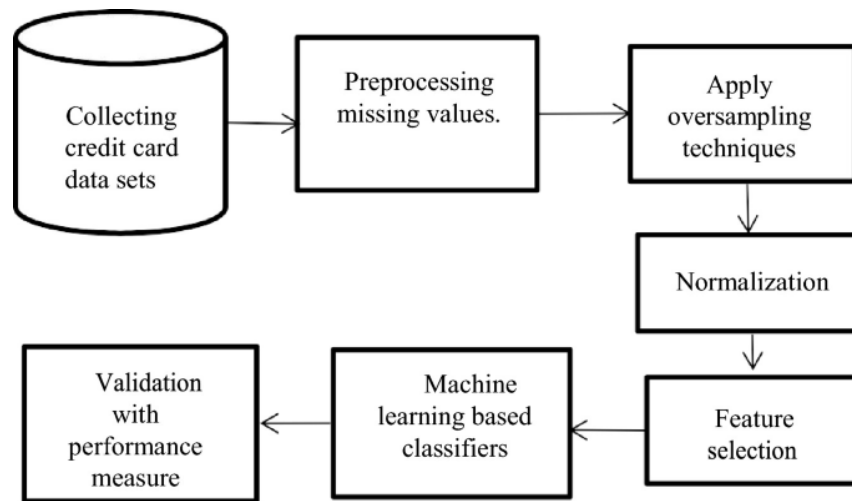

Fig: Project plan.

**The project will be completed in different phases:**

### **Data collection:**

The first phase will involve collecting a dataset of historical credit card transactions. The data will be collected from a variety of sources, including banks, credit card companies, and merchants.

### **Data Cleaning:**

- Impute the missing values with the mean, median, or mode of the column.
- Drop the rows with missing values.
- Use a machine learning model to predict the missing values like `isnull()`, `heatmap()`.

### **Normalize the data:**

Normalization is the process of scaling the data so that all of the features have a similar range of values. This can help to improve the performance of machine learning models by making the features more comparable.

### **Model training:**

The second phase will involve training the machine learning model on the collected data. The model will be trained using a supervised learning algorithm, such as SVM.

## Model evaluation:

The third phase will involve evaluating the performance of the machine learning model on a holdout dataset of unseen transactions. The performance of the model will be evaluated using metrics such as accuracy, precision, and recall.

## Timeline for Our Project:

## Results and Evaluations

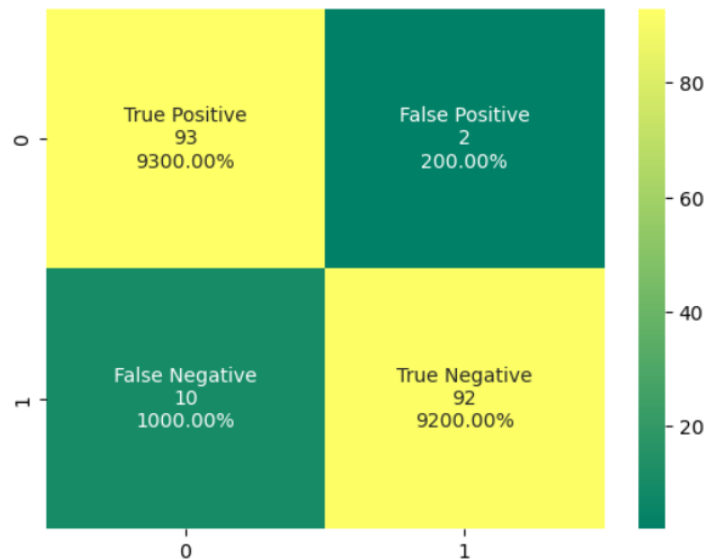

### Expected Result:

- A machine learning model that can detect credit card fraud with high accuracy.
- A better understanding of the patterns that are indicative of fraudulent transactions.
- A framework for using machine learning to detect credit card fraud in real-time.

### Performance Metrics and Evaluation Methodology:

#### Confusion Metrics:

A Confusion matrix is an N x N matrix used for evaluating the performance of a classification model, where N is the number of target classes. The matrix compares the actual target values with those predicted by the machine learning model.

#### Classification Report:

	precision	recall	f1-score	support
0	0.90	0.98	0.94	95
1	0.98	0.90	0.94	102
accuracy			0.94	197
macro avg	0.94	0.94	0.94	197
weighted avg	0.94	0.94	0.94	197

## Conclusion:

In this project, credit card fraud detection was performed using four different machine learning models: **Logistic Regression**, **K-Nearest Neighbors (KNN)**, **Support Vector Machine (SVM)**, and **Decision Tree**. The dataset used consists of real credit card transactions, where each transaction is labeled as **fraudulent (Class = 1)** or **legitimate (Class = 0)**. A major challenge of this dataset is its **highly imbalanced nature**, with fraud transactions forming only a very small fraction of the total data. To address this issue, **undersampling and oversampling (SMOTE)** techniques were applied to balance the dataset before training the models.

**Logistic Regression** was used as a baseline model due to its simplicity and interpretability. After applying feature scaling and handling class imbalance, the model showed reasonable performance. However, while accuracy appeared high, it was observed that accuracy alone was misleading. The model's strength lay in its ability to provide probabilistic outputs, but it required careful balancing of data to improve **recall**, which is crucial in fraud detection.

**K-Nearest Neighbors (KNN)** was implemented as a distance-based classifier. Since KNN relies on distance calculations, feature scaling was essential. After undersampling, KNN demonstrated improved fraud detection capability compared to the imbalanced case. However, KNN was computationally expensive and sensitive to noise, and its performance depended heavily on the choice of the number of neighbors ( $k$ ). Although it achieved decent recall, it was less scalable for large datasets.

**Support Vector Machine (SVM)** showed strong performance in separating fraud and non-fraud transactions. By using the **RBF kernel**, SVM was able to handle non-linear decision boundaries effectively. After undersampling and scaling, SVM achieved a good balance between **precision and recall**, which was further validated using **ROC and Precision-Recall curves**. SVM proved to be robust and effective for fraud detection, though it required higher computational resources and careful parameter tuning.

**Decision Tree** provided the advantage of easy interpretability by clearly showing the decision-making process. When trained on undersampled and SMOTE-balanced data, the Decision Tree improved fraud detection performance, especially in terms of recall. However, it was prone to overfitting, particularly when the tree depth was not controlled. Despite this, Decision Trees were useful for understanding feature importance and decision logic.

Overall, the experiments demonstrated that **handling class imbalance is more important than model selection alone**. Metrics such as **precision, recall, F1-score, confusion matrix, ROC curve, and Precision-Recall curve** provided a more reliable evaluation than accuracy. Among the models, **SVM and Decision Tree (with proper sampling)** showed strong performance in detecting fraudulent transactions, while Logistic Regression and KNN served as effective baseline and comparative models. The study concludes that combining proper data preprocessing with suitable evaluation metrics significantly enhances fraud detection performance.
